Standard, Word, and Expanded Form to 1,000

Answer Key

Grade 2–3 Mathematics

Quick Answers

1. 546	4. 907	7. 615	10. 375
2. 372	5. 605	8. 78, 708, 780	
3. 284	6. —	9. 470	

Common wrong answers

7. If they got 6015: wrote the hundreds digit and then the whole number fifteen side by side instead of regrouping it as 1 ten and 5 ones

1. Write 546 in expanded form.

Name the value of each digit by its place, then add those values: the 5 sits in the hundreds place and is worth 500, the 4 sits in the tens place and is worth 40, the 6 sits in the ones place and is worth 6.

$\boxed{546 = 500 + 40 + 6}$

2. Write $300 + 70 + 2$ in standard form.

Each part of an expanded form names one place. 300 fills the hundreds place with a 3, 70 fills the tens place with a 7, and 2 fills the ones place. Reading the digits in order gives the standard form.

$\boxed{372}$

3. Write two hundred eighty-four in standard form.

Read the name in chunks. "Two hundred" is 200, "eighty" is 80, and "four" is 4. Those are the three place values, so $200 + 80 + 4$ is the expanded form and the digits are 2, 8, 4.

$\boxed{284}$

4. Write 907 in expanded form.

Hundreds: 900. Tens: the digit is 0, so the tens place is worth nothing here and is left out. Ones: 7. A place holding a zero still needs its digit in standard form — it just contributes nothing to the sum.

$\boxed{907 = 900 + 7}$

Grading note: an answer of $90 + 7$ means the student read the 9 as 9 tens. Ask which place the 9 is sitting in.

5. Write $600 + 5$ in standard form.

There is no tens part in the expanded form, so the tens place is empty and must be held open with a 0; otherwise the 5 would slide over into the tens place and make 65.

$\boxed{605}$

6. Which is greater, $400 + 30 + 9$ or four hundred ninety-three?

Put both numbers in standard form first — you cannot compare a sum with a number name by looking at them. $400 + 30 + 9 = 439$, and four hundred ninety-three is 493. Both have 4 hundreds, so compare the next place: 3 tens against 9 tens. Since $3 < 9$, the first number is smaller.

$\boxed{439 < 493}$

7. Maya wrote six hundred fifteen as 6015. Fix it.

Maya wrote the 6 for "six hundred" and then wrote "fifteen" as the two digits 15 beside it, giving four digits. But "fifteen" is not a new place — it is 1 ten and 5 ones, which fill the tens and ones places of the same three-digit number.
Hundreds = 6, tens = 1, ones = 5, so the expanded form is $600 + 10 + 5$.

$\boxed{615}$

Grading note: 6015 is the diagnostic wrong answer — it means the student is stacking chunks side by side instead of assigning each chunk to a place. Have them build the number with base-ten blocks: 6 flats, 1 rod, 5 units.

8. Order $700 + 8$, seven hundred eighty, and 78 from least to greatest.

Convert everything to standard form first: $700 + 8 = 708$, seven hundred eighty = 780, and 78 is already in standard form.
Now compare. 78 has only two digits, so it is the smallest. Both 708 and 780 have 7 hundreds, so compare tens: 0 tens against 8 tens, and $0 < 8$.

$\boxed{78 < 708 < 780}$

9. Write 470 in word form and in expanded form.

Word form (read the digits by place): **four hundred seventy**. There is no "and" in a whole-number name, and the 0 ones are not spoken.
Expanded form: hundreds 400, tens 70, ones 0 — and a zero part is dropped from the sum.

$\boxed{470 = 400 + 70}$

Manual review: the spelling of the number name is read by a teacher; only the expanded form is machine-checked.

10. Challenge: start with $300 + 60 + 5$, add ten more.

Step 1 — standard form of the starting number: $300 + 60 + 5 = 365$.
Step 2 — ten more means one more ten, so the tens digit goes from 6 to 7: $365 + 10 = 375$. Nothing else changes, because adding a ten only touches the tens place (there is no regrouping here: $6 + 1 = 7$ still fits in one digit).
Step 3 — expanded form of the new number: $300 + 70 + 5$.

$\boxed{375 = 300 + 70 + 5}$
