

# Telling Exponential Change from Linear Change

---

Constant differences against constant ratios, evaluating both models, and comparing them over the long run

## Directions

- One test settles which model a table follows: over equal steps in the input, a **linear** pattern has equal *differences* between outputs, and an **exponential** pattern has equal *ratios*.
  - Linear rules look like  $a + bx$ ; exponential rules look like  $a \cdot r^x$ , where  $r$  is the number you multiply by at each step.
  - Round money and population answers to two decimal places where a decimal appears.
  - Where a problem asks you to compare two models, use the numbers you computed as the evidence.
- 

1. A table of a function:

|     |   |   |    |    |
|-----|---|---|----|----|
| $x$ | 0 | 1 | 2  | 3  |
| $y$ | 5 | 9 | 13 | 17 |

(a) Subtract consecutive outputs.  $9 - 5 = \underline{\hspace{2cm}}$

(b) Divide consecutive outputs.  $9 \div 5 = \underline{\hspace{2cm}}$

(c) Which model does this table follow, linear or exponential? Justify your choice from the numbers in (a) and (b).

**2.** A different table:

|     |   |    |    |     |
|-----|---|----|----|-----|
| $x$ | 0 | 1  | 2  | 3   |
| $y$ | 6 | 18 | 54 | 162 |

(a) Divide consecutive outputs.  $18 \div 6 = \underline{\hspace{2cm}}$

(b) Subtract the first pair.  $18 - 6 = \underline{\hspace{2cm}}$

(c) Subtract the next pair.  $54 - 18 = \underline{\hspace{2cm}}$

**3.** Let  $f(x) = 4 + 6x$  and  $g(x) = 4 \cdot 2^x$ . Both start at 4 when  $x = 0$ .

(a)  $f(5) = \underline{\hspace{2cm}}$

(b)  $g(5) = \underline{\hspace{2cm}}$

**4.** A town of 200 people is modelled two ways. Model  $L$  adds 30 people each year. Model  $E$  multiplies by 1.15 each year, a 15% rise.

(a) Population after 4 years under model  $L$ :  $\underline{\hspace{2cm}}$

(b) Population after 4 years under model  $E$ , to two decimal places:  $\underline{\hspace{2cm}}$

5. A table of a decaying quantity:

|     |    |    |    |    |
|-----|----|----|----|----|
| $x$ | 0  | 1  | 2  | 3  |
| $y$ | 80 | 40 | 20 | 10 |

(a) Divide consecutive outputs.    ratio = \_\_\_\_\_

(b) Continue the pattern.    value at  $x = 4$ : \_\_\_\_\_

6. Let  $f(x) = 50 + 20x$  and  $g(x) = 5 \cdot 2^x$ .

(a)  $f(4) =$  \_\_\_\_\_    (b)  $g(4) =$  \_\_\_\_\_

(c)  $f(8) =$  \_\_\_\_\_    (d)  $g(8) =$  \_\_\_\_\_

**7.** Two savings plans each start with \$500. Plan  $A$  adds \$40 every month. Plan  $B$  grows by 6% every month, so it multiplies by 1.06 each month.

(a) Value of plan  $A$  after 12 months, in dollars: \_\_\_\_\_

(b) Value of plan  $B$  after 12 months, in dollars to two decimal places: \_\_\_\_\_

(c) Which plan is worth more after a year? Explain whether that advantage grows, shrinks, or stays the same as the years go on.

**8.** Let  $g(x) = 3 \cdot 2^x$ . Solve  $g(x) = 96$ . (Write  $96 \div 3$  as a power of 2 first.)

Answer: \_\_\_\_\_

**9.** A car bought for \$24,000 is valued two ways. The straight-line method subtracts \$2400 every year. The percentage method multiplies by 0.88 every year, a 12% loss.

(a) Value after 5 years, straight-line method: \_\_\_\_\_

(b) Value after 5 years, percentage method, to two decimal places: \_\_\_\_\_

**10.** Let  $f(x) = 100 + 25x$  and  $g(x) = 100 \cdot 1.2^x$ . They start together at 100.

(a)  $f(3) =$  \_\_\_\_\_ (b)  $g(3) =$  \_\_\_\_\_

(c)  $f(4) =$  \_\_\_\_\_ (d)  $g(4) =$  \_\_\_\_\_

(e) At which whole-number input does  $g$  first become the larger of the two? Justify your answer using the four values above.
