

# Graphing Proportional Relationships

## Answer Key

Grades 6–7 Ratios and Proportional Relationships

### Quick Answers

---

- |             |              |            |        |
|-------------|--------------|------------|--------|
| 1. 8, 8     | 4. 2.5       | 7. 3, 2    | 10. 18 |
| 2. 2.5, 2.5 | 5. 8         | 8. 16, 4   |        |
| 3. 3        | 6. 5, 4, 3.5 | 9. 3.5, 42 |        |
- 

### Common wrong answers

---

3. If they got 0.333333: read the point backwards and divided time by distance
- 

#### 1. Dog-walking pay: plot the table and find the unit rate.

**Step 1.** The three points are (0, 0), (3, 24) and (5, 40). Plotted, they lie on one straight line, and that line starts at the origin — the mark of a proportional relationship.

**Step 2.** Unit rate from the origin to (3, 24):  $k = \frac{24 - 0}{3 - 0} = 8$ .

**Step 3.** Check between two points that are not the origin:  $k = \frac{40 - 24}{5 - 3} = \frac{16}{2} = 8$ . The same rate everywhere is what makes the graph a straight line through (0, 0).

*Manual review:* the plotted points and the drawn line are the student's own work — check that all three points are placed correctly and the line is ruled through the origin. Dev earns 8 dollars per hour.  $k = 8$

#### 2. Rice cost: plot the table and find the cost of one kilogram.

**Step 1.** Points (0, 0), (2, 5) and (6, 15). All three lie on one line through the origin, so cost is proportional to mass.

**Step 2.** From the origin to (2, 5):  $k = \frac{5}{2} = 2.5$ .

**Step 3.** Between the two non-origin points:  $\frac{15 - 5}{6 - 2} = \frac{10}{4} = 2.5$  — the same constant.

*Manual review:* inspect the student's plotted points and ruled line. One kilogram of rice costs 2.5 dollars.  $k = 2.5$

#### 3. Cyclist graph: unit rate in kilometres per hour.

**Step 1.** The line goes through the origin, so the unit rate is  $y \div x$  at any point on it. Use the marked point (5, 15).

**Step 2.**  $k = \frac{15}{5} = 3$  kilometres per hour.

*Common wrong answer:* 0.33, from dividing hours by kilometres. Always put the quantity named by the  $y$ -axis on top.  $k = 3$

**4. Paint graph: write the equation.**

**Step 1.** A line through the origin has the form  $y = kx$ , so the only thing to find is  $k$ .

**Step 2.** The marked point is  $(4, 10)$ , so  $k = \frac{10}{4} = 2.5$  square metres per litre.

**Step 3.** Substituting the constant gives the equation  $y = 2.5x$ .

$$y = 2.5x$$

**5. Barrel: how long to collect 12 litres.**

**Step 1.** The equation is  $y = 1.5x$ , and the question fixes the output at  $y = 12$ , so solve  $1.5x = 12$  for  $x$ .

**Step 2.**  $x = \frac{12}{1.5} = 8$  minutes.

**Step 3.** The graph agrees: reading across from 12 litres meets the line above 8 minutes.

$$x = 8$$

**6. Is the relationship proportional?**

**Step 1.** Divide  $y$  by  $x$  in every column. If the relationship is proportional, all the quotients are the same number.

**Step 2.**  $5 \div 1 = 5$ ,  $8 \div 2 = 4$ ,  $14 \div 4 = 3.5$ .

**Step 3.** The three quotients are different, so there is no single constant of proportionality. The graph settles it too: the line is straight but it meets the  $y$ -axis at 2, not at the origin, so it is not a proportional relationship.

5, 4, 3.5 : not proportional

**7. Two runners: both unit rates and who is faster.**

**Step 1.** Both lines pass through the origin, so each unit rate is  $y \div x$  at that line's marked point.

**Step 2.** Runner A through  $(4, 12)$ :  $\frac{12}{4} = 3$  metres per second. Runner B through  $(5, 10)$ :  $\frac{10}{5} = 2$  metres per second.

**Step 3.** The steeper line has the larger unit rate, so runner A is faster — by 1 metre per second.

$$A = 3, B = 2$$

**8. Water tank: difference between two readings, and the unit rate.**

**Step 1.** Read the marked points: at 1 minute the tank holds 4 litres, at 5 minutes it holds 20 litres.

**Step 2.** Difference:  $20 - 4 = 16$  litres more.

**Step 3.** Unit rate:  $\frac{20 - 4}{5 - 1} = \frac{16}{4} = 4$  litres per minute, which matches  $y \div x$  at either point.

$$16, k = 4$$

**9. Bottling machine: unit rate, then a prediction off the graph.**

**Step 1.** The marked point is  $(4, 14)$  and the line goes through the origin, so  $k = \frac{14}{4} = 3.5$  hundreds of bottles per hour.

**Step 2.** The equation is  $y = 3.5x$ .

**Step 3.** At  $x = 12$  hours:  $y = 3.5 \times 12 = 42$  hundreds of bottles. The drawn axis stops at 6 hours, which is exactly why the equation is worth having.

$$k = 3.5, y = 42$$

**10. Printer: draw the graph, then find the time for 45 pages.**

**Step 1.** 5 pages every 2 minutes is a unit rate of  $\frac{5}{2} = 2.5$  pages per minute, so the equation is  $y = 2.5x$  and the graph is the line through  $(0, 0)$  and  $(20, 50)$ .

**Step 2.** Set the output to 45 pages:  $2.5x = 45$ .

**Step 3.**  $x = \frac{45}{2.5} = 18$  minutes. On the graph, 45 pages sits between the gridlines at 40 and 50, above 18 minutes.

*Manual review:* the drawn line is the student's own work — it must start at the origin and pass through  $(4, 10)$  and  $(20, 50)$ .

|          |
